

PROGRAMMAZIONE PROCEDURALE

A.A. 2025/2026

STRUCTURES

STRUCTS

- ④ Arrays allow to define type of variables that can hold several data items of the same kind. Similarly **structure** is another user defined data type available in C that allows to combine data items of different kinds.
- ④ Structures are used to represent a record. Suppose you want to keep track of your books in a library. You might want to track the following attributes about each book –
 - ✓ Title
 - ✓ Author
 - ✓ Subject
 - ✓ Book ID
- ④ To access the fields of a structure, use “.”

```
struct [tag_name] { member_declaration_list };
```

DEFINITION OF STRUCTURES

- ④ To define a structure, you must use the **struct** statement. The struct statement defines a new data type.

```
struct [tag] {  
  
    member definition;  
    member definition;  
  
    member definition;  
};
```

```
struct Song {  
    char title[64];  
    char artist[32];  
    char composer[32];  
    short duration;  
    struct Date published;  
};
```

NAME SPACES

- ④ The tags of structure types are a distinct name space: the compiler distinguishes them from variables or functions whose names are the same as a structure tag.
- ④ Likewise, the names of structure members form a separate name space for each structure type.
- ④ Uppercase helps you to understand when it is a struct.

MEMBERS

- Ⓢ The members of a structure may have any desired complete type, including previously defined structure types. They must not be variable-length arrays.

```
struct Song {
    char title[64];
    char artist[32];
    char composer[32];
    short duration;
    struct Date published;
};

struct Date {
    short int day;
    short int month;
    short int year;
};
```

- Ⓢ A structure type cannot contain itself as a member, as its definition is not complete until the closing brace (}).

EXAMPLE

```
struct Song {  
    char title[64];  
    char artist[32];  
    char composer[32];  
    short duration;  
    struct Song similar;  
};
```

EXAMPLE

```
#include <stdio.h>
#include <string.h>

struct Books {
    char title[50];
    char author[50];
    char subject[100];
    int book_id;
};

int main( ) {

    struct Books Book1;          /* Define Book1 of type Book */
    struct Books Book2;          /* Define Book2 of type Book */

    /* book 1 specification */
    strcpy( Book1.title, "C Programming");
    strcpy( Book1.author, "Nuha Ali");
    strcpy( Book1.subject, "C Programming Tutorial");
    Book1.book_id = 6495407;
    /* print Book1 info */
    printf( "Book 1 title : %s\n", Book1.title);
    printf( "Book 1 author : %s\n", Book1.author);
    printf( "Book 1 subject : %s\n", Book1.subject);
    printf( "Book 1 book_id : %d\n", Book1.book_id);

    return 0;
}
```

SELF REFERENTIAL STRUCTURES

- ⊙ However, structure types can and often do contain pointers to their own type.
- ⊙ Such *self-referential structures* are used in implementing linked lists, for example.

```
struct Cell { struct Song song;           // This record's data.  
              struct Cell *pNext;       // A pointer to the next record.  
};
```

EXAMPLE

```
typedef struct S {  
    int x;  
} T;
```

OR

```
struct S {  
    int x;  
};
```

```
typedef struct S T;
```

```
struct S var1;
```

```
T var2;
```

FUNCTIONS AND STRUCTS

```
#include <stdio.h>
#include <string.h>

struct Books {
    char title[50];
    char author[50];
    char subject[100];
    int book_id;
};

void printBook( struct Books book ) {
    printf( "Book title : %s\n", book.title);
    printf( "Book author : %s\n", book.author);
    printf( "Book subject : %s\n", book.subject);
    printf( "Book book_id : %d\n", book.book_id);
}

/* function declaration */
void printBook( struct Books book );

int main( ) {

    struct Books Book1;          /* Declare Book1 of type Book */

    /* book 1 specification */
    strcpy( Book1.title, "C Programming");
    strcpy( Book1.author, "Nuha Ali");
    strcpy( Book1.subject, "C Programming Tutorial");
    Book1.book_id = 6495407;

    /* print Book1 info */
    printBook( Book1 );

    return 0;
}
```

```
scanf("%s", &book1.title)
scanf("%d", &book1.book_id)
```

POINTERS AND STRUCTS

- ④ You can define pointers to structures in the same way as you define pointer to any other variable

```
struct Books {
    char title[50];
    char author[50];
    char subject[100];
    int book_id;
};

int main() {
    struct Books *struct_pointer;
    struct Books Book1;
    struct_pointer = &Book1;

    // commands
}
```

ACCESSING STRUCTURE MEMBERS

- ② Two operators allow you to access the members of a structure object: the dot operator (.) and the arrow operator (->). Both of them are binary operators whose right operand is the name of a member.
- ② -> is a shortcut instead of
✓ (*pointer_to_structure).field

Precedence	Operators	Associativity
1.	Postfix operators: [] () . -> ++ -- (<i>type name</i>){ <i>list</i> }	Left to right
2.	Unary operators: ++ -- ! ~ + - * &	Right to left

EXAMPLE

```
struct Books {  
    char title[50];  
    char author[50];  
    char subject[100];  
    int book_id;  
};
```

```
int main() {  
    struct Books *struct_pointer;  
    struct Books Book1;  
    struct_pointer = &Book1;
```

```
(*struct_pointer).book_id= 1 // Primo esempio per accedere  
struct_pointer->book_id = 1 // Secondo esempio  
}
```

COPY STRUCTURES

- ④ You can use an assignment to copy the entire contents of a structure object to another object of the same type:
 - ✓ Books book1, book2; book2 = book1;
- ④ After this assignment, each member of book2 has the same value as the corresponding member of book1.

INITIALIZATION LIST

- ④ To initialize a structure object explicitly when you define it, you must use an *initialization list*: this is a comma-separated list of *initializers*, or initial values for the individual structure members, enclosed in braces.
 - ✓ The initializers are associated with the members in the order of their declarations
 - ✓ Each initializer must have a type that matches (or can be implicitly converted into) the type of the corresponding member

EXAMPLE

```
struct Date {
    short int day;
    short int month;
    short int year;
};

struct Song { char title[64];
              char artist[32];
              char composer[32];
              short duration;
              struct Date published;
};
```

```
int main () {

    struct Song mySong = { "What It Is",
                          "Aubrey Haynie",
                          "Mark Knopfler",
                          297,
                          { 26, 9, 2000 }
    };

    // commands
}
```

INITIALIZING SPECIFIC MEMBERS

- ④ You can explicitly associate an initializer with a certain member.
- ④ To do so, you must prefix a *member designator* with an equal sign to the initializer. The general form of a designator for the structure member *member* is:

✓ *.member* // Member designator

```
Song_t aSong = { .title = "I've Just Seen a Face",  
                .composer = "John Lennon; Paul McCartney",  
                127 };
```

- ④ 127 is the initialization of the first field after “composer”, i.e., “duration”.

ARRAYS OF STRUCT

```
struct Song { char title[64];
              char artist[32];
              char composer[32];
              short duration;
              struct Date published;
};

int main () {

    struct Song array_of_songs[100];

    // commands
}
```

SIZEOF OF A STRUCT

```
#include <stdio.h>
struct Song {
    char title[64];
    char artist[32];
    char composer[32];
    short duration;
};

int main () {

    struct Song songVar;

    printf("La dimensione di una struttura Song in bytes e': %ld", sizeof(songVar));
}
MacBook-Francesco:Programmi francescosantini$
./esempio
La dimensione di una struttura Song in bytes e': 130
```

UNIONS

WHAT UNIONS ARE

- ④ Unlike structure members, which all have distinct locations in the structure, **the members of a *union* all share the same location in memory:**
- ④ All members of a union start at the same address.
- ④ Thus you can define a union with many members, **but only one member can contain a value at any given time.**
- ④ Unions are an easy way for programmers to use a location in memory in different ways.

DEFINITION

- ⊙ The definition of a union is formally the same as that of a structure, except for the keyword `union` in place of `struct`:
 - ✓ *`union [tag_name] { member_declaration_list };`*
- ⊙ An object of this type can store an integer, a floating-point number, or a short string.
 - ✓ `union Data { int i; double x; char str[16]; };`
- ⊙ A union is big as its largest member.
 - ✓ Using our example, `sizeof(union Data)` yields the value 16.

DIFFERENCE IN MEMORY WRT STRUCTS

```
union Data { int i; double x; char str[16]; };
```

```
struct Data { int i; double x; char str[16]; };
```

EXAMPLE

```
union Data { int i; double x; char str[16]; };
```

```
var.x = 3.21;  
var.x += 0.5;  
strcpy( var.str, "Jim" );  
myData[0].i = 50;
```

INITIALIZING UNIONS

- ⊙ Like structures, union objects are initialized by an *initialization list*. For a union, though, the list can only contain one *initializer*.
- ⊙ If the initializer has no member designator, then it is associated with the first member of the union.

```
union Data var1 = { 77 },  
            var2 = { .str = "Mary" },  
            var3 = var1,  
            myData[100] = { {.x= 0.5}, { 1 }, var2 };
```

EXAMPLE

```
#include <stdio.h>
#include <string.h>

union Data {
    int i;
    float f;
    char str[20];
};

int main( ) {

    union Data data;

    printf( "Memory size occupied by data : %d\n", sizeof(data));

    return 0;
}
```

Memory size occupied by data :
20

EXAMPLE

```
#include <stdio.h>
#include <string.h>

union Data {
    int i;
    float f;
    char str[20];
};

int main( ) {

    union Data data;

    data.i = 10;
    printf( "data.i : %d\n", data.i);

    data.f = 220.5;
    printf( "data.f : %f\n", data.f);

    strcpy( data.str, "C Programming");
    printf( "data.str : %s\n", data.str);

    return 0;
}
```

data.i : 10
data.f : 220.500000
data.str : C Programming

EXAMPLE

```
#include <stdio.h>
#include <string.h>

union Data {
    int i;
    float f;
    char str[20];
};

int main( ) {

    data.i : 1917853763
    data.f : 4122360580327794860452759994368.000000
    data.str : C Programming

    union Data data;

    data.i = 10;
    data.f = 220.5;
    strcpy( data.str, "C Programming");

    printf( "data.i : %d\n", data.i);
    printf( "data.f : %f\n", data.f);
    printf( "data.str : %s\n", data.str);

    return 0;
}
```
