# PROGRAMMAZIONE PROCEDURALE

A.A. 2023/2024

## **LITERALS**

#### **LITERALS**

- A literal is a token that denotes a fixed value, which may be an integer, a floating-point number, a character, or a string.
- A literal's type is determined by its value and its notation.

#### **INTEGER CONSTANTS**

- An integer constant can be expressed as an ordinary decimal numeral, or as a numeral in octal or hexadecimal notation.
- You must specify the intended notation by a prefix.
  - ✓ base-8 number system?
  - $\checkmark$ 0, 1, 2, 3, 4, 5, 7 -> 8<sup>n</sup> x+8<sup>n-1</sup> + ... + 8<sup>1</sup> + 8<sup>0</sup>
- A decimal constant begins with a nonzero digit
- Q A number that begins with a leading zero is interpreted as an octal constant. 047 = ?
  - $\checkmark$ 39 = (4 x 8<sup>1</sup> + 7 x 8<sup>0</sup>)
- A hexadecimal constant begins with the prefix 0x or 0X.
   Hexadecimal digits A to F can be upper or lowercase.
  - ✓0xff, 0Xff, 0xFF, and 0XFF = 15 x 16<sup>1</sup> + 15 x 16<sup>0</sup> = 255

#### **TYPE OF CONSTANTS**

- The type of a constant is determined at the same time as its value is defined.
- Integer constants such as the examples just mentioned usually have the type int. If larger:
  - ✓ The compiler assigns it the first type in a hierarchy that is large enough to represent the value.
- For example, a short is 2 byte2, the decimal constant 50000 has the type int, since the greatest possible short value is 32,767, or 2<sup>15</sup>– 1.
- You can also influence the types of constants in your programs explicitly by using suffixes.
  - √512U (unsigned int), 0Xf0fUL (unsigned long), 0777II (long long), 123uLL (unsigned long long)

### **EXAMPLES**

```
int a= 512U;
int b= 1LL;
int c= 7UL;
```

Uppercase or lowercase is the same, e.g., II or LL

#### **FLOATING-POINT CONSTANTS**

- Floating-point constants can be written either in decimal or in hexadecimal notation.
- A floating-point constant consists of a sequence of decimal digits containing a decimal point.
- You may also multiply the value by a power of 10, as in scientific notation: the power of 10 is represented simply by an exponent, introduced by the letter e or E.
  - $\checkmark$ 2.34E5 (2.34 x 10<sup>5</sup>), 67e-12 (67.0 x 10<sup>-12</sup>)
- The decimal point can also be the first or last character.
  Thus 10. and .234E6 are permissible numerals.
  - ✓ However, the numeral 10 with no decimal point would be an integer constant, not a floating-point constant.

#### FORCING THE TYPE OF FLOATS

- The default type of a floating-point constant is double.
- You can also append the suffix F or f to assign a constant the type float, or the suffix L or I to give a constant the type long double

#### **CHARACTER CONSTANTS**

A character constant consists of one character enclosed in single quotation marks.

To represent ', \ and newline

Character constants have the type int

## **ESCAPE SEQUENCES**

Escape sequence	Character value	Action on output device
\'	A single quotation mark (')	Prints the character.
\"	A double quotation mark (")	
\?	A question mark (?)	
\\	A backslash character (\)	
<b>\</b> a	Alert	Generates an audible or visible signal.
<b>\</b> b	Backspace	Moves the active position back one character.
\f	Form feed	Moves the active position to the beginning of the next page.
<b>\</b> n	Line feed	Moves the active position to the beginning of the next line.
\r	Carriage return	Moves the active position to the beginning of the current line.

#### **STRING LITERALS**

- A string literal consists of a sequence of characters
   (and/or escape sequences) enclosed in double quotation
   marks.
  - ✓"Hello world!\n"
- Q Like character constants, string literals may contain all the characters in the source character set.
- A string literal is a static array of char that contains character codes followed by a string terminator, the null character \0.
- The empty string "" occupies exactly one byte in memory, which holds the terminating null character.

```
char helloWorld[128] = "Hello World!\n";
printf("Print the string: %s\n", helloWorld);
```
